

README – Feedback Function and Performance on Variable Differential Reinforcement of Low Rates: Tempus Urgit vel Abundat? (analysis scripts + outputs)

Project overview

This folder contains the R code used to (a) decode MED-PC event files, (b) compute and model inter-response time (IRT) survival functions (VI and VDRL), and (c) analyze/visualize feedback functions (including a mixed-effects Hill fit) and response-rate summaries/plots.

Directory structure

JEAB_25/

 decoder.R

 - Core decoder for MED-PC outputs. Reads raw session files and returns a standardized event-level data frame (subject, session, event, time_stamp, etc.).

 survival.R

 - Survival analysis at the individual level (per rat), including:
 - subject-specific refractory-time correction (minimum positive IRT)
 - Kaplan-Meier curves and piecewise exponential fits
 - figure export for individual survival panels
 - Produces: Figures/Figure9.png

 survival_agg.R

 - Aggregated survival analysis:
 - Aggregates IRTs across selected sessions per subject
 - Applies refractory-time correction (shift by min positive IRT)
 - Estimates global breakpoints via PWEXP (MLE)
 - VDRL inference: compares CoxPH vs CoxME (1|subject) using LR Chi-square
 - Plotting overlay: fits a piecewise-exponential mixed model via survSplit + glmer
 to obtain segment hazards (lambdas) for the black model overlay line
 - Computes segment proportions (prop_1, prop_2, prop_3) from the empirical IRTs
 - Excludes subject JL1 ONLY for the aggregated VDRL analysis (as specified)
 - Produces: Figures/Figure10.png (VDRL survival + overlay + breakpoints)

Figures/Figure8.png (VI survival + overlay +
breakpoint)

- Prints: Cox model comparison (VDRL) + final parameter
table (VI + VDRL)

feedback_function.R

- Feedback-function analysis and figure production.
- Includes:
- computing/plotting feedback functions
- fitting/visualizing candidate equations
- Hill function definition and a mixed-effects Hill
model (nlme)
- spaghetti (random-effects) curves and fixed-effect
curve + simulated CI band
- Produces multiple figure files inside Figures/ (see
"Figures" section below).

response_rates.R

- Response-rate analysis using ResponseRates.xlsx:
- violin plots by condition
- Gaussian LMM vs Gamma GLMM comparison
- post-hoc emmeans contrasts
- individual time-series panel plot (per rat)
- Produces: Figures/Figure7.png (panel plot)

full_dataframe.R

- Utility script to build a combined "full_data" data
frame from decoded files.
- Helpful for downstream analyses that need a single long-
format data set.

SomeTrials.R

- Exploratory / scratch script (non-essential). Kept for
transparency.

get_r2_nlme.R

- Helper function to compute R^2 -like metrics for nlme
models.
- Called by feedback_function.R when evaluating the mixed
Hill fit.

MedScript/

VDRL.txt

- MED-PC script/program used to run the VDRL procedure.

data/

simulation_beak/

RDRL10_JL_b_hdi.xlsx

- Spreadsheet used for a simulation / auxiliary
analysis (not required for the

main survival pipeline unless explicitly referenced elsewhere).

Figures/

- Output folder for exported PNG figures created by the scripts above.

Software requirements

R (recommended: >= 4.2)

Core packages used across scripts:

survival
PWEXP
lme4
coxme
nlme
MASS
scales
dplyr
tidyr
readxl
vioplot
performance
emmeans
car
multcomp

Note:

- Some scripts call ``source("decoder.R")`` and assume the working directory is the project root (JEAB_25/).
- Some scripts write PNGs to "Figures/". Make sure this folder exists.

Data requirements/assumptions

1) Raw MED-PC event files:

- The survival scripts expect raw session files to exist in paths like:

data/rats/VDRL10s/
data/rats/VI30s/

and they are decoded by decoder.R.

- If these folders are not present in your shared archive, you must add them

locally (or update the paths in the scripts) to reproduce survival results.

2) Response-rate spreadsheet:

- response_rates.R expects:

ResponseRates.xlsx
in the project root (or update the file path).

Reproducing the main results (recommended order)

1) Aggregated survival analysis (final survival figures + parameter table)

- Run:

```
source("survival_agg.R")
```

- Outputs:

Figures/Figure10.png (VDRL aggregated survival + model overlay + breakpoints)

Figures/Figure8.png (VI aggregated survival + model overlay + breakpoint)

and prints the Cox model comparison + parameter table to the console.

Important details implemented in survival_agg.R:

- JL1 is excluded ONLY for the aggregated VDRL analysis.

- Breakpoints are estimated empirically via PWEXP MLE (nbreak = 2 for VDRL, 1 for VI).

- The black model overlay line is computed from the piecewise-exponential mixed model

(survSplit + glmer) using fixed-effect segment hazards (lambdas).

2) Individual survival panels (optional)

- Run:

```
source("survival.R")
```

- Output:

```
Figures/Figure9.png
```

3) Feedback-function analysis (Hill mixed model + related figures)

- Run:

```
source("get_r2_nlme.R")
```

```
source("feedback_function.R")
```

- Outputs:

Multiple figures inside Figures/ (see console messages and the png() calls in

feedback_function.R for exact filenames).

4) Response-rate analysis and time-series panels

- Ensure ResponseRates.xlsx is present.

- Run:

```
source("response_rates.R")
```

- Output:

```
Figures/Figure7.png
```

Notes on key modeling choices

- Refractory-time correction:

For each subject (within the selected sessions), the smallest strictly positive IRT is treated as a refractory bound. In the aggregated survival pipeline, IRTs are shifted by subtracting this refractory time and then filtered to remain strictly positive.

- Breakpoints:

Breakpoints are estimated from aggregated IRTs using PWEXP maximum-likelihood fitting:

- VDRL: two breakpoints (three segments)
- VI: one breakpoint (two segments)

- VDRL inference vs visualization:

In `survival_agg.R`, VDRL inference for clustering is based on a CoxPH vs. CoxME comparison.

The black overlay line, however, is drawn from a piecewise-exponential mixed model

(`survSplit + glmer`) to obtain segment hazards (λ s) for a clean parametric survival curve overlay on the Kaplan-Meier estimate.

Agreement analysis

Agreement analysis, used in Figures 3 and 4, was done using `eirasagree` (R package), available at: <https://doi.org/10.7910/DVN/AGJPZH>

Contact/citation

If you use or adapt these scripts, please cite the associated manuscript (JEAB submission) and acknowledge the code archive (this folder) as the computational supplement.
